

# Nomenclature of the Human Immunoglobulin Kappa (IGK) Genes

Marie-Paule Lefranc

IMGT Nomenclature Committee, CNRS, Université Montpellier II, Montpellier, France

## Key Words

Human · IMGT · Immunoglobulin ·  
Kappa chain genes · Orphans

## Abstract

'Nomenclature of the Human Immunoglobulin Kappa (IGK) Genes', the 17th report of the 'IMGT Locus in Focus' section, provides the first complete list of all the human IGK genes. In the most frequent haplotypes, the human IGK locus spans 1,820 kb and the IGKV genes are organized in two clusters separated by 800 kb. In those haplotypes where both the proximal and distal IGKV clusters are present, the total number of human IGK genes per haploid genome is 82 (107 genes if the orphans are included) of which 37–41 are functional. If only the proximal IGKV cluster is present, which is found in a rare haplotype, the total number of genes per haploid genome is 46 (71 genes if the orphans are included) of which 23–25 genes are functional. IMGT/HUGO gene names and definitions

of the human IGK genes on chromosome 2p11.2, and IGK orphans on chromosomes 1, 2, 15, and 22 are provided with the gene functionality and the number of alleles according to the rules of the IMGT Scientific chart, with the accession numbers of the IMGT reference sequences, and the accession ID of the Genome Database GDB and NCBI LocusLink databases in which all the IMGT human IGK genes have been entered. The tables are available at the IMGT Marie-Paule page from **IMGT**, the international ImMunoGeneTics database (<http://imgt.cines.fr:8104>) created by Marie-Paule Lefranc, Université Montpellier II, CNRS, France.

**Fig. 1.** Chromosomal localization of the human IGK locus at 2p11.2. A vertical line indicates the localization of the IGK locus at 2p11.2. The arrow indicates the orientation 5' → 3' of the locus, and the gene group order in the locus. The arrow is proportional to the size of the locus, indicated in kilobases. The total number of genes in the locus is shown between parentheses; the lower number (46 genes) corresponds to the rare haplotype which only comprises the proximal V-CLUSTER of 40 IGKV genes, whereas the higher number (82 genes) corresponds to the common haplotype which comprises both the distal and the proximal V-CLUSTERS and 76 IGKV genes. The number of functional genes defines the potential IGK repertoire which comprises 37–41 genes (31–35 IGKV, 5 IGKJ, and 1 IGKC) per haploid genome if both the proximal and distal V-CLUSTER are present. In the rare haplotype with only the proximal V-CLUSTER, the potential IGK repertoire comprises 23–25 genes (17–19 IGKV, 5 IGKJ, and 1 IGKC) per haploid genome [18].

mental and Clinical Immunogenetics [1–17]. This report comprises three tables and three figures entitled, respectively: (1) ‘Complete list of the human IGK genes on chromosome 2 at 2p11.2’; (2) ‘Human IGK orphans on chromosomes 1, 2, 15, and 22’; (3) ‘Correspondence between the human IGKV gene nomenclatures’; (4) ‘Chromosomal localization of the human IGK locus at 2p11.2’; (5) ‘Representation of the human IGK locus at 2p11.2’, and (6) ‘The CLASSIFICATION concept of the IMGT-ONTOLOGY exemplified for the IGKV genes’. The tables provide the first complete list of all the human IGK genes. In the most frequent haplotypes, the human IGK locus spans 1,820 kb and the IGKV genes are organized in two clusters separated by 800 kb. In those haplotypes where both the proximal and distal IGKV clusters are present the total number of human IGK genes per haploid genome is 82 (107 genes if the orphans are included) of which 37–41 are functional. If only the proximal IGKV cluster is present, which is found in a rare haplotype, the total number of genes per haploid genome is 46 (71 genes if the orphans are included) of which 23–25 genes are functional. IMGT/HUGO gene names and definitions of the human IGK genes on chromosome 2p11.2, and IGK orphans on chromosomes 1, 2, 15, and 22 are provided with the gene functionality and the number of alleles, according to the rules of the IMGT Scientific chart, with the accession numbers of the IMGT reference sequences, and the accession ID of the Genome Database GDB and NCBI LocusLink databases in which all the IMGT human IGK genes have been entered. Detailed references for individual IGKV, IGKJ, and IGKC genes are available in references 3, 7, and 18. These tables and figures are available at the IMGT Marie-Paule page from **IMGT**, the international ImMunoGeneTics database (<http://imgt.cines.fr:8104>) created by Marie-

#### *Human IGK Locus at 2p11.2*

The human IGK locus is located at band 2p11.2 [22] of the short arm of chromosome 2 [23] (fig. 1). The orientation of the locus has been determined by the analysis of translocations, involving the IGK locus, in leukemia and lymphoma.

The human IGK locus at 2p11.2 spans 1,820 kb (fig. 2). It consists of 76 IGKV genes [3, 7, 24–29] belonging to 7 subgroups, 5 IGKJ segments [30], and a unique IGKC gene [31] (table 1). In the most frequent haplotypes, the 76 IGKV genes are organized in two clusters separated by 800 kb. The IGKV distal cluster (in 5' of the locus and in the most centromeric position) spans 400 kb and comprises 36 genes. The IGKV proximal cluster (in 3' of the locus, closer to IGKC, and in the most telomeric position) spans 600 kb and comprises 40 genes. The potential genomic IGK repertoire comprises 31–35 functional IGKV genes belonging to 5 subgroups, the 5 IGKJ segments, and the unique IGKC gene. One rare IGKV haplotype has been described which contains only the proximal cluster. This haplotype comprises the 40 proximal IGKV genes belonging to 7 subgroups, of which 17–19 are functional and belong to 5 subgroups. If both the proximal and distal IGKV clusters are present, the total number of human IGK genes per haploid genome is 82 (107 genes if the orphans are included) of which 37–41 are functional [18]. If only the proximal IGKV cluster is present, the total number of genes per haploid genome is 46 (71 genes if the orphans are included) of which 23–25 genes are functional [18].

#### **Orphans**

Twenty-five IGKV orphans have been identified and sequenced: one on chromosome 1, 2 on the short arm of chromosome 2 but outside of the main IGK locus, 12 on the long arm of chromosome 2, one on chromosome 15, 5 on chromosome 22, and 4 outside of chromosome 2 [3] (table 2).

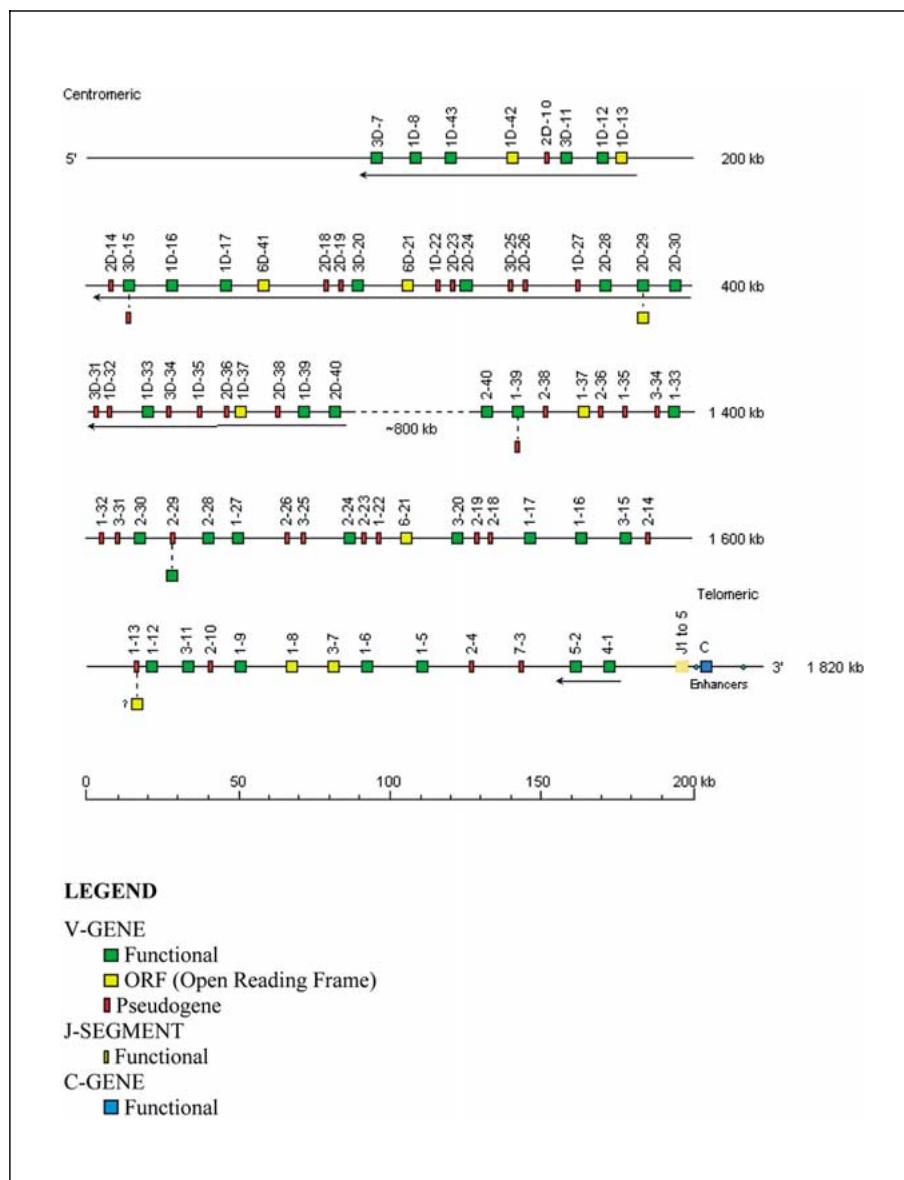

#### **IGK Gene Nomenclature and IMGT Scientific Chart**

##### *Gene Names*

Gene names (tables 1, 2) are according to the IMGT gene name nomenclature for Ig and TcR of all vertebrates based on the ‘CLASSIFICATION’ concept of the IMGT-ONTOLOGY [32] (Appendix), and according to the rules of the IMGT Scientific chart [19, 21] available at <http://imgt.cines.fr:8104>. IMGT gene names and IMGT gene definitions for the human Ig [33] and TcR genes [34] have been approved by the Human Genome Organization (HUGO) Nomenclature Committee in 1999. Note that, in the HUGO symbols (<http://www.gene.ucl.ac.uk/nomenclature>), slashes and parentheses are omitted, and capital letters replace the lowercase letters found in some provisional IMGT gene names. Otherwise the gene symbols and all the full names (including slashes and parentheses) are identical in IMGT and HUGO nomenclatures.

##### *Functionality*

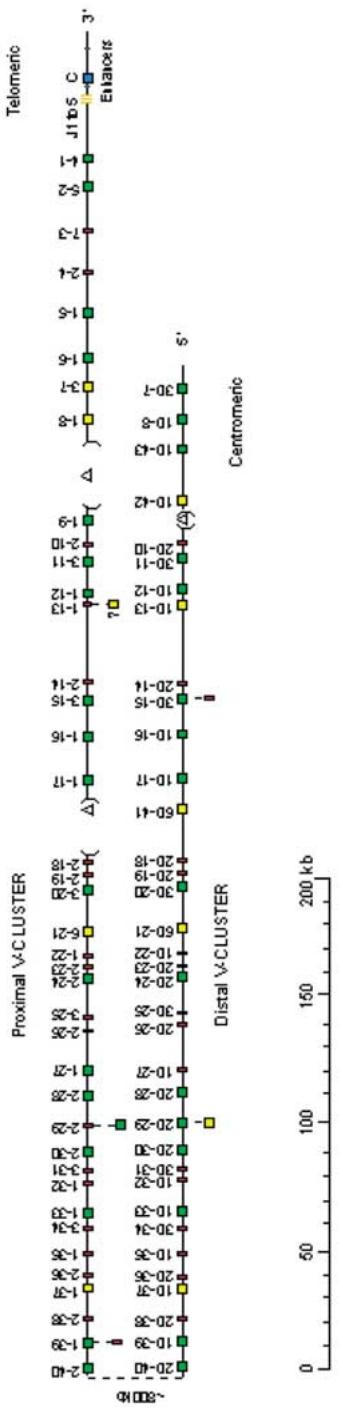

Criteria of functionality (F: Functional, P: Pseudogene, ORF: Open Reading Frame) (tables 1, 2) have been described in the IMGT Scientific chart [1]. The definition of functionality is based on sequence analysis. As examples, the instances functional (for germline V, D, J, and for C sequences) mean that

**Fig. 2.** Representation of the human IGK locus at 2p11.2. The boxes representing the genes are not to scale. Exons are not shown. The IGKV genes of the proximal V-CLUSTER are designated by a number for the subgroup, followed by an hyphen and a number for the localization from 3' to 5' in the locus. The IGKV

genes of the distal duplicated V-CLUSTER are designated by the same numbers as the corresponding genes in the proximal V-CLUSTER, with the letter D added. Arrows show the IGKV gene polarity of which is opposite to that of the J-C-CLUSTER.

**Alternative representation of the human IGK locus, taking into account the polymorphic duplication in the locus (see references 24–27).**

*Small triangles indicate parts which are absent in the proximal or distal V-CLUSTER when considering the duplication in the human IGK locus.*

the coding regions have an open reading frame without a stop codon, and that there is no described defect in the splicing sites, and/or recombination signals, and/or regulatory elements. According to the gravity of the identified defects, functionality can be defined as ORF, pseudogene or vestigial (for germline V, D, J, and for C genes) [1]. Complete definitions are available in the IMGT Scientific chart at the IMGT Marie-Paule page. Information on gene rearrangement, DNA transcription into mRNA, and RNA translation into a polypeptide chain is provided in the IMGT ‘Germline gene tables’ in the IMGT Repertoire (columns designated as R, T, and Pr, respectively), and has been published in a previous ‘IMGT Locus in Focus’ report [3]. This information is extracted from the literature and through IMGT/LIGM-DB sequence database search [20, 21]. The IMGT/V-QUEST tool, available at the IMGT Home page at <http://imgt.cines.fr:8104>, allows the identification of the germline IGKV, and IGKJ genes from IGKV-J genomic rearrangements and transcripts, and provides translation and a two-dimensional representation (Collier de Perles) of the variable regions [20, 21, 35].

#### Reference Sequences

For each gene, an IMGT reference sequence accession number is given (tables 1, 2). For the functional or ORF genes, the IMGT reference sequence accession number is that corresponding to allele\*01. Note that the number \*01 does not necessarily mean that other alleles are already known, but it signifies that any new polymorphic sequence will be described by comparison to that allele \*01. Although the IMGT accession numbers are the same as those from the EMBL/GenBank/DDBJ general databases, the content of the IMGT/LIGM-DB flat files differs by the expert annotations, added by IMGT.

**Table 1.** Complete list of the human IGK genes on chromosome 2 at 2p11.2

IGKV gene nomenclature: IGKV genes are designated by a number for the subgroup, followed by an hyphen and a number for the localization from 3' to 5' in the locus. The IGKV genes of the distal duplicated V-CLUSTER are designated by the same number as the corresponding genes in the proximal V-CLUSTER, with the letter D added.

(1) Note that in the HUGO symbols, slashes of the orphan names are omitted. Otherwise the gene names (gene symbols) are identical in IMGT and HUGO nomenclatures.

(2) Gene definitions (full names) are identical (including slashes) in IMGT and HUGO nomenclatures.

(3) Other entries concerning the IGK orphans in the OMIM, GDB, and LocusLink genome databases, and in HUGO:

IMGT designation	IMGT definition	OMIM	GDB	LocusLink	HUGO
IGKV/OR2	Immunoglobulin kappa variable orphans on chromosome 2	147185	GDB:128324	3524	IGKVOR2@

**Alleles**

The number of alleles of the human IGKV, IGKJ and IGKC genes (tables 1, 2) is according to *Tables of alleles* and *Alignments of alleles*, in the IMGT Repertoire, at <http://imgt.cines.fr:8104>. A dash (-) indicates that allele polymorphism of the pseudogenes has not been studied. Alignments of all known germline functional and ORF sequences assigned to the different alleles, by comparison to the allele \*01, are displayed in reference [18]. Human IGK entries in reference 18 include 51 genes and 66 alleles, with a total of 142 sequences.

**Genome Database Accession Numbers**

All IMGT/HUGO human IGK gene symbols, full names and reference sequence accession numbers have been entered into Genome Database GDB, Toronto, Canada (<http://www.gdb.org>), and into LocusLink at NCBI (National Center for Biotechnology Information), Bethesda, USA (<http://www.ncbi.nlm.nih.gov/LocusLink>). Accession ID to these genome databases are provided in tables 1 and 2. Links to OMIM (Online Mendelian Inheritance in Man, MIM) (<http://www.ncbi.nlm.nih.gov/Omim>) are cited when there are entries in OMIM. Links to the individual IMGT, GDB and LocusLink gene entries are available from <http://imgt.cines.fr:8104> from IMGT Repertoire > List of human Ig and TcR genes > Immunoglobulins.

**Correspondences between Nomenclatures and Numberings**

Correspondence between the human IGKV gene nomenclatures is reported in table 3.

In order to easily compare sequences of immunoglobulins and T cell receptors, a unique numbering has been defined for the

The IGKV genes of the proximal V-CLUSTER are designated by a number for the subgroup, followed by an hyphen and a number for the localization from 3' to 5' in the locus. The IGKV genes of the distal duplicated V-CLUSTER are designated by the same numbers as the corresponding genes in the proximal V-CLUSTER, with the letter D added. Homologous genes in the proximal and distal V-CLUSTER are on the same line. Boxes are empty when no homologous gene is found in the other cluster.

variable regions [35, 36]. Correspondence between the IMGT unique numbering and other numberings for the human IGKV genes is available from the IMGT Scientific chart and reference 35. The IMGT unique numbering relies on the high conservation of the structure of the variable region. This numbering takes into account and combines the definition of the framework (FR) and complementarity determining regions (CDR) [37], structural data from X-ray diffraction studies [38], and the characterization of the hypervariable loops [39]. The unique numbering has allowed the redefinition of the limits of the FR and CDR [35]. The FR-IMGT and CDR-IMGT lengths themselves become crucial information characterizing the variable regions belonging to a group, a subgroup, and/or a gene. For example, for a germline gene of the human IGKV1 subgroup, the lengths of the 3 CDR-IMGT, in number of amino acids is designated as [6.3.7] (IMGT Repertoire > 2D and 3D structures) [7, 35]. The unique numbering is used as the output of the IMGT/V-QUEST alignment tool, and in the *Alignments of alleles* (IMGT Repertoire > Proteins and alleles) [18].

## Acknowledgments

I thank Gérard Lefranc, Ruth Lovering, Donna Maglott, Chris Porter, Sue Povey, Conover Talbot and all the immunologist colleagues for their contribution to the IMGT Nomenclature Committee. I am grateful to Valérie Contet for the editorial work. IMGT is funded by the European Union's BIOTECH (BIO4CT96-0037) and 5th PCRDT (QLG2-2000-01287) programs, the Centre National de la Recherche Scientifique (CNRS), Ministère de la Recherche, and Ministère de l'Education Nationale. Subventions have been received from the Association pour la Recherche sur le Cancer (ARC), and Région Languedoc-Roussillon.

## Appendix

### *The 'CLASSIFICATION' Concept of the IMGT-ONTOLOGY*

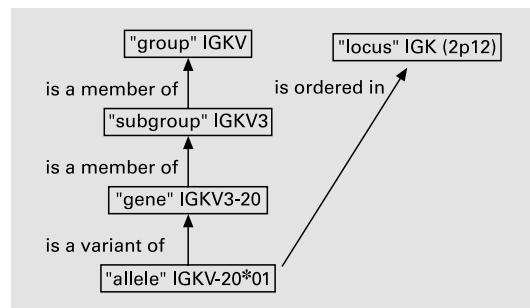

The 'CLASSIFICATION' concept of the IMGT-ONTOLOGY (fig. 3) organizes immunogenetics knowledge useful to name and classify the immunoglobulin genes [32].

**Locus:** A locus is a group of immunoglobulin genes that are ordered and localized in the same chromosomal location in a given species. 'Locus' IGK (2p12) is one of the three main immunoglobulin loci in the human genome. Immunoglobulin genes have also been identified in other chromosomal locations outside the main loci which represent new instances of the locus concept. However, the genes they contain, designated as orphans, are not functional.

**Group:** A group is a set of genes which share the same 'gene type' (V, D, J or C) and participate potentially in the synthesis of a polypeptide of the same 'chain type'. By extension, a group includes the related pseudogenes and orphans. A 4-letter root designates the 'group': for example, IGKV, IGKJ, and IGKC for the immunoglobulin kappa genes.

**Subgroup:** A subgroup is a set of genes which belong to the same group in a given species and share at least 75% identity at the nucleotide level (in the germline configuration for V, D, and J). For example, the IGKV genes belong to 7 subgroups.

**Gene:** A gene is defined as a DNA sequence that can be potentially transcribed and/or translated (this definition includes the regulatory elements in 5' and 3', and the introns, if present). Instances of the 'gene' concept are gene names. By extension, orphans and pseu-

**Fig. 3.** The 'CLASSIFICATION' concept of the IMGT-ONTOLOGY, exemplified for the IGKV genes.

dogenes are also instances of the ‘gene’ concept. For each gene, IMGT has defined a reference sequence [19]. For the V, D, and J genes, the reference sequence corresponds to a germline entity. The rules for the choice of the reference sequences are described at <http://imgt.cines.fr:8104> in the IMGT Scientific chart.

**Allele:** An allele is a polymorphic variant of a gene. Alleles are described, exhaustively and in a standardized way, for the four ‘core’ coding regions, that

is the germline V-REGIONS, D-REGIONS, and J-REGIONS, and for the C-REGIONS, from immunoglobulin genes. These alleles refer to sequence polymorphisms, with mutations described at the sequence level [1]. Their sequences are compared to the reference sequence designated as \*01 (see IMGT Scientific chart at <http://imgt.cines.fr:8104> for IMGT description of mutations, and IMGT allele nomenclature for sequence polymorphisms).
